YANG and NETCONF

**YET ANOTHER NEXT
GENERATION**

NIL Network Management Characteristics

Device 1:
Vendor A
Model X
Version 1.2

Device 2:
Vendor A
Model X
Version 1.4

Device 3:
Vendor A
Model Y
Version 1.3

Device 4:
Vendor B
Model Z
Version 9.5

...

Device 1233:
Vendor W
Model T
Version F

- Different management interfaces
- Different capabilities
 - CLI for configuration, SNMP for monitoring, HTTP for RBAC...

Device 1:
Vendor A
Model X
Version 1.2

Device 2:
Vendor A
Model X
Version 1.4

Device 3:
Vendor A
Model Y
Version 1.3

Device 4:
Vendor B
Model Z
Version 9.5

...

Device 1233:
Vendor W
Model T
Version F

- Learn all management interfaces
- Understand the capabilities and limitations of each device group
- Ensure consistency and reliability of configurations
- Backup configurations (and restore if/when needed)

SNMP!

Device 1:
Vendor A
Model X
Version 1.2

Device 2:
Vendor A
Model X
Version 1.4

Device 3:
Vendor A
Model Y
Version 1.3

Device 4:
Vendor B
Model Z
Version 9.5

...

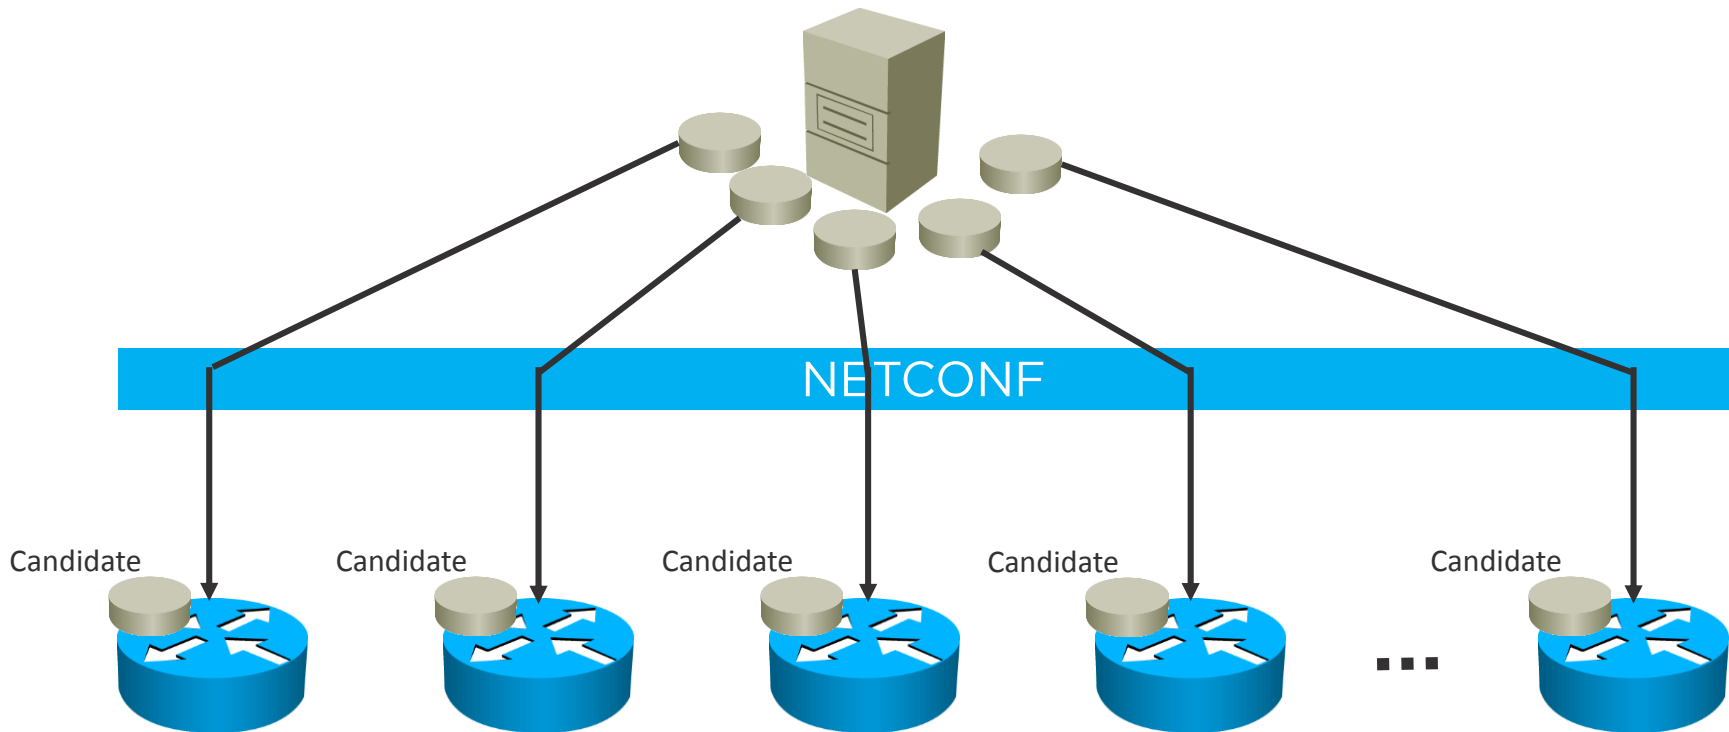

Device 1233:
Vendor W
Model T
Version F

- Good intentions, but poor result in practice
- Today, SNMP is primarily only used for monitoring
- Possible reasons:
 - Most IETF standards are influenced by network equipment vendors
 - Operators' input was missing in determining what features are required for efficient network management

- Ease of use!
- Clearly separating configuration from other data
- Ability to compare across devices
- Service and network management, not device management
- Network wide transactions
- Devices figure out ordering
- No unnecessary changes
- Backup and restore of configuration
- Validation of configuration which should be text based
- Standardized data models
- Support for multiple configuration sets
- Delayed, orchestrated activation
- Role-Based Access Control (RBAC): data and task oriented

- Candidate data stores enable data-wide transactions:
 - [Send configuration changes](#) to all participating devices
 - [Commit candidates](#) if all participating devices successfully validate changes

Legacy Network Management

Operations

Vs.

Hardware

- Lack of atomicity
- Ordering problem

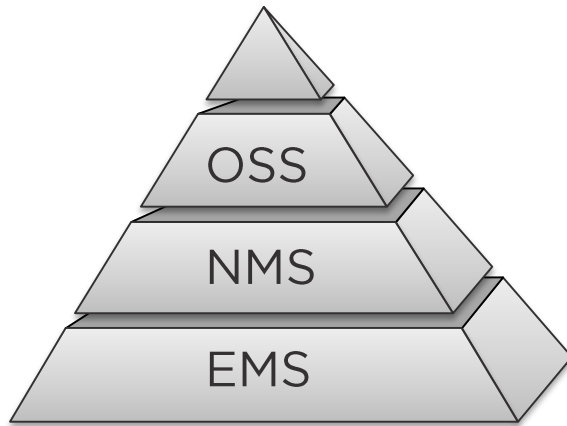

Transactional Network Management

Operations

Vs.

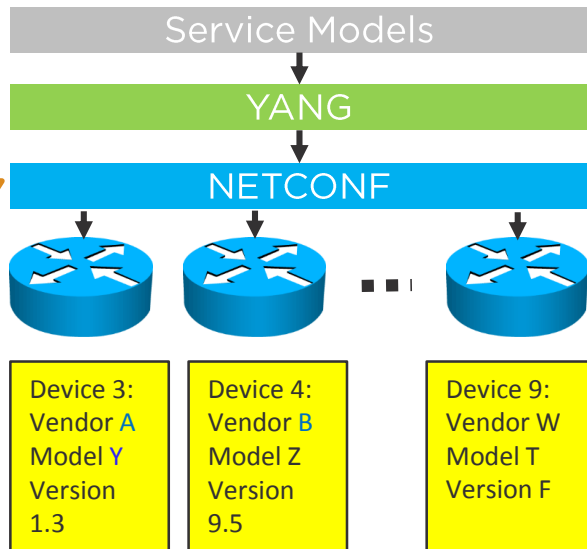

Hardware

"YANG is a data modeling language used to model configuration and state data manipulated by the Network Configuration Protocol (NETCONF), NETCONF remote procedure calls, and NETCONF notifications. YANG is used to model the operations and content layers of NETCONF"

IETF RFC 6020

The **NETCONF** protocol allows a manager to set configuration, query configuration and state and execute actions on the device (similar to SNMP).

The **YANG** models describe everything there is to ...

- Configure
- Monitor
- Admin actions
- Notifications

... for each device type and version (similar to MIBs).

- Designed for [readability](#)
- Uses UTF-8 encoding to support international character sets
- Simplicity enables fast service model development
- Modularity and hierarchy enable reuse of code

```
list loopback-interface {  
  key Loopback;  
  unique ip-address;  
  
  leaf Loopback {  
    type string;  
  }  
  
  leaf ip-address {  
    type uint32;  
  }  
}
```

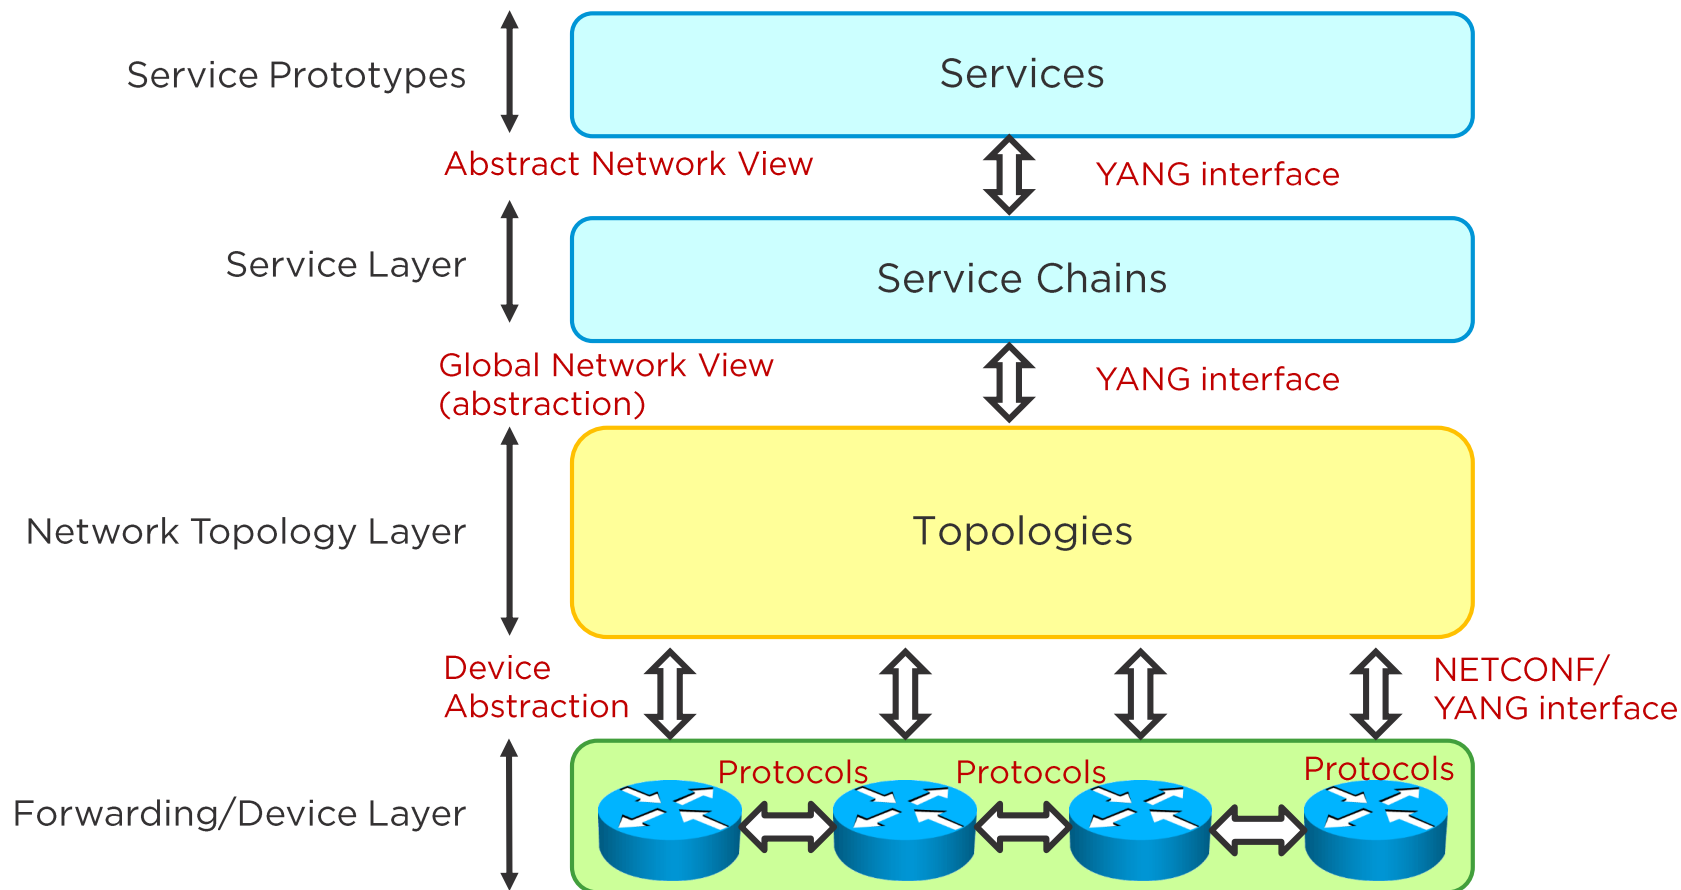

```
<list name="loopback-interface">  
  <key value="Loopback"/>  
  <unique tag="ip-address"/>  
  <leaf name="Loopback">  
    <type name="string"/>  
  </leaf>  
  <leaf name="ip-address">  
    <type name="uint32"/>  
  </leaf>  
</list>
```

The Power of Abstractions

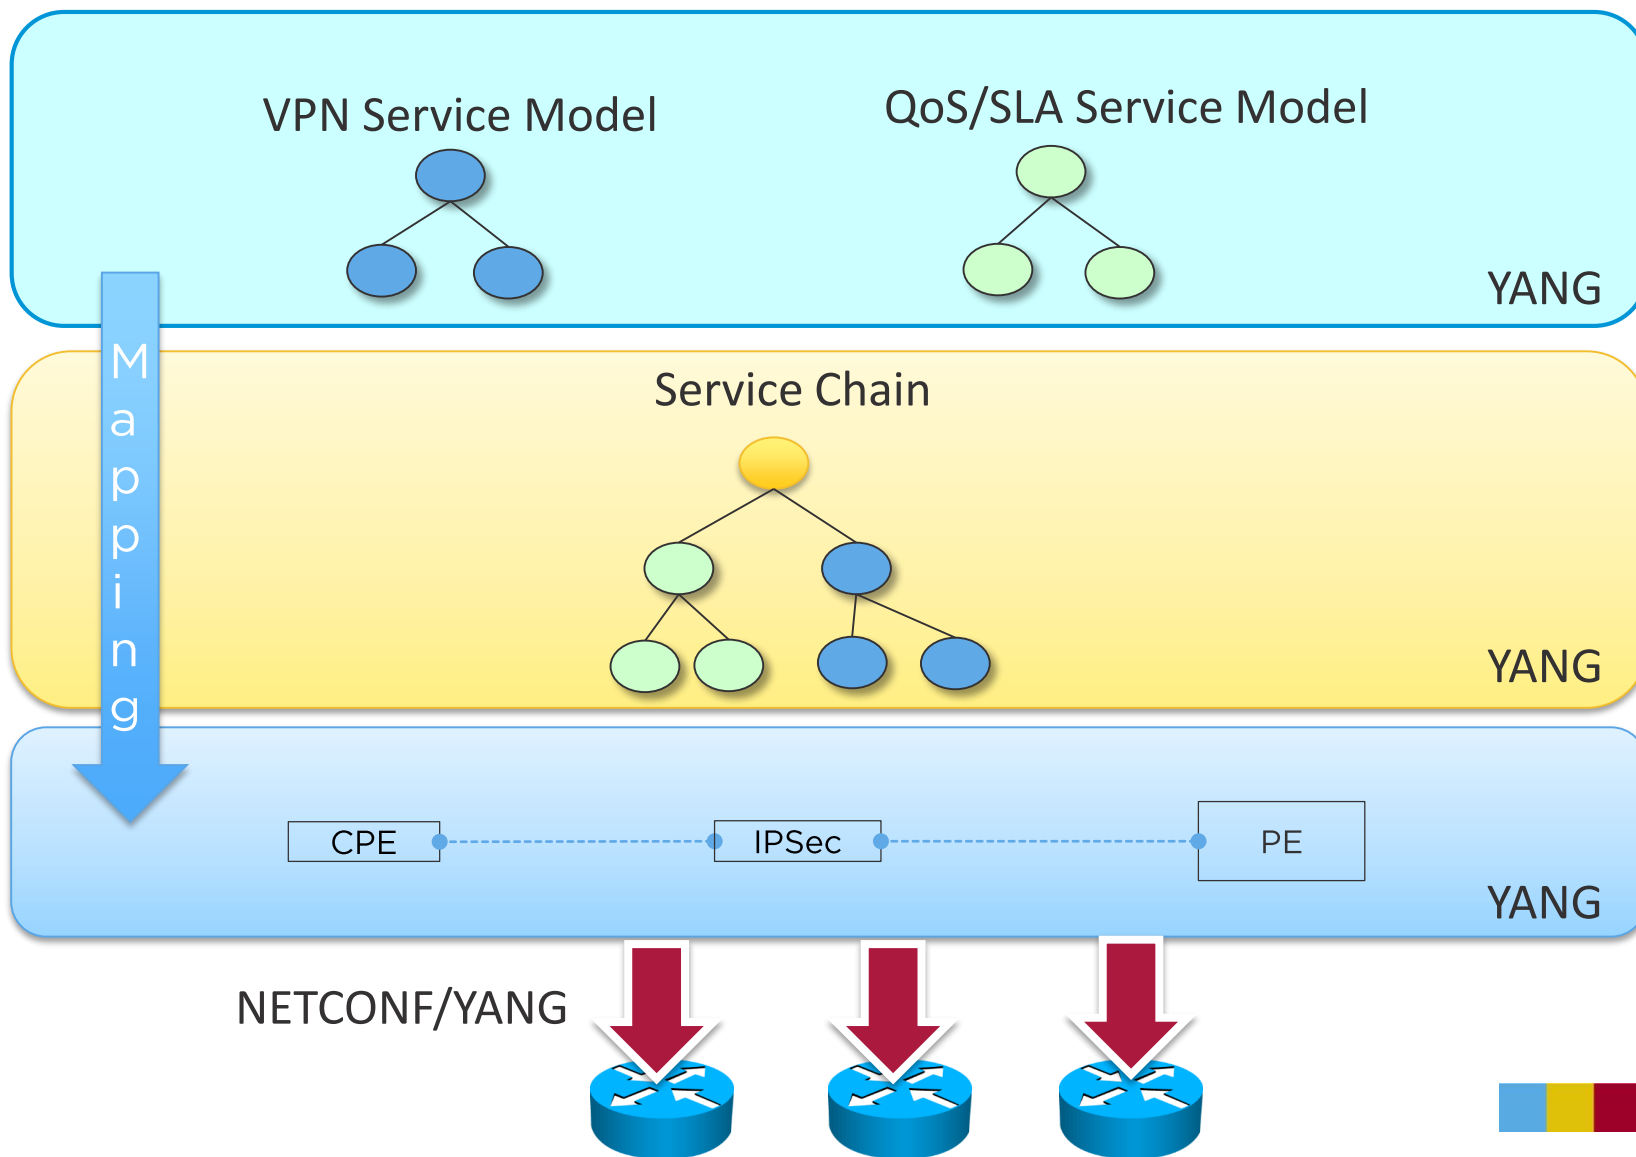

- Networking currently lacks fundamental abstractions
- As a result, networks are hard to manage
- Abstractions simplify and speed up development
- YANG can provide a global network view abstraction

Layered Architecture

Example

- The protocol is mature (survived 10+ years)
- Can effectively replace CLI/other interfaces
- Abstractions can be done on many levels
- Configurational integrity is guaranteed
- Provides complete and partial rollbacks
- Provides network wide transactions
- Simplifies configuration management and service lifecycle management
- Service chaining is much easier to implement
- Enables truly modular service design
- Enables reusability of service components
- Reduces complexity of multi-domain network orchestration

- Actual support varies from vendor to vendor
 - Danger of poor implementation
- In order to maintain transaction based management, different agents have to be implemented (ConfD...) for non-NETCONF devices
 - Implementation quality varies!
 - Requires additional CPU/Memory!
- YANG models can become very large - memory implications
- YANG still requires certain extensions (30+ open drafts)
- Device-level YANG models require standardisation
- NETCONF/YANG are designed for configuration management in mind
 - Changes are less dynamic than operational
 - What about network monitoring?
